

ABSTRACT OF THE DISCLOSURE

An on-line product delivery and billing system for aggregating product content delivery and payment for a network of customers and content providers is described. A content provider dynamically creates product content from one or more suppliers. The content provider sets pricing levels for the product content and aggregates billing information for the one or more suppliers and provides the content and payment information to the customer. The customer is billed for product delivery based upon predefined customer parameters and usage. The customer is presented one bill for all publishers' content accessed over the network. Upon payment the content provider provides payment to the suppliers in accordance with pre-established terms and conditions. Alternatively, the customer pays the suppliers directly, using the network as a delivery, metering, and billing platform. The product content is modified for transmission to specific customer client devices.
